

Security risk assessment report

After inspecting the organization's network, you discover four major vulnerabilities. The four vulnerabilities are as follows:

1. The organization's employees' share passwords.
2. The admin password for the database is set to the default.
3. The firewalls do not have rules in place to filter traffic coming in and out of the network.
4. Multi Factor authentication (MFA) is not used.

Part 1: Select up to three hardening tools and methods to implement

I'm going to suggest we implement an MFA tool similar to the DUOMobile at my school at FGCU. We need to put password policies into place with absolutely no tolerance for shared passwords and are more specific on what information can be used. This should also be applied to the Admin password set to default. We need to set up rules for the firewall and also maintain an IPS to not only filter traffic but also to prevent any incoming attacks that could potentially damage the network. The last thing would be a SIEM tool

Part 2: Explain your recommendations

My recommendation is that you use the tools, I mentioned above such as an IPS, SIEM tool, and stronger password policies with MFA to fix the vulnerabilities that are currently setting our social media company up with many risks for data breaches that may occur.
